

Fundamental Algorithm Techniques – Problem Set #10

Problem 1 — P, NP, NP-complete, NP-hard

Definitions (short & simple)

- **P**: problems solvable in **polynomial time**
- **NP**: solutions can be **verified** in polynomial time
- **NP-complete**: hardest problems **inside NP**
- **NP-hard**: at least as hard as NP-complete, may not be in NP
- **Undecidable**: cannot be solved by any algorithm

1. find max, linear search, shortest path in unweighted graph, matrix multiplication

All have **polynomial-time algorithms**.

Class: P

2. sorting of list, Dijkstra (non-negative), BFS, DFS, merge sort, quicksort

All are classic **efficient algorithms**.

Class: P

3. Sudoku

- Checking a solution → polynomial
- Finding a solution → hard

Class: NP-complete

4. 3-coloring of graph, scheduling with conflicts

Both are classic NP-complete problems.

Class: NP-complete

5. Traveling Salesperson Problem, Hamiltonian Cycle, Clique

All are famous hard problems in NP.

Class: NP-complete

6. Cryptography, factoring large integers

- Verification is easy
- No known polynomial-time solution

Class: NP (not known to be P or NP-complete)

7. Halting Problem, Busy Beaver

No algorithm can solve these in general.

Class: Undecidable

Problem 2 — Bayes Theorem

Bayes Theorem

Problem 2

$$P(D) = 0.001 \text{ (0.1\%)}$$

Test accuracy:

1) Sensitivity = 99% $\rightarrow P(+|D) = 0.99$

2) Specificity = 99% $\rightarrow P(-|\neg D) = 0.99$

$$P(+|\neg D) = 0.01$$

$$\text{Bayes: } P(D|+) = \frac{P(+|D)P(D)}{P(+|D)P(D) + P(+|\neg D)P(\neg D)}$$

$$P(D|+) = \frac{0.99 \cdot 0.001}{0.99 \cdot 0.001 + 0.01 \cdot 0.999} = \frac{0.00099}{0.01098} \approx 0.09$$

$$\underline{P(D|+) \approx 9\%}$$

Explanation:

Even accurate tests give many false positives when the disease is rare.

Optional Python code

```
P_D = 0.001
P_not_D = 1 - P_D
P_pos_given_D = 0.99
P_pos_given_not_D = 0.01

P_D_given_pos = (P_pos_given_D * P_D) / (
    P_pos_given_D * P_D + P_pos_given_not_D * P_not_D
)

print("Probability patient has disease:", round(P_D_given_pos * 100, 2), "%")
```

Problem 3 — Shannon Entropy

problem 3. Shannon Ent.

$$H(X) = -\sum_i p_i \log_2 p_i$$

coin A (fair one)

$$p = (0.5, 0.5)$$

$$H = -[0.5 \log_2 0.5 + 0.5 \log_2 0.5] = 1$$

$$H = 1 \text{ bit}$$

coin B (99% heads (open))

$$p = (0.99, 0.01)$$

$$H \approx 0.08 \text{ bits}$$

coin C (1% heads)

$$p = (0.01, 0.99)$$

$$H \approx 0.08 \text{ bits}$$

same

Explanation

- Fair coin $\rightarrow$ maximum uncertainty $\rightarrow$ **1 bit**
- Biased coin $\rightarrow$ predictable $\rightarrow$ **few bits**

- Rare events → **huge surprise**, but **low average entropy**

Python code

```
import math
```

```
def entropy(p):  
    return -sum(pi * math.log2(pi) for pi in p if pi > 0)
```

```
coins = {  
    "Fair coin": [0.5, 0.5],  
    "99% heads": [0.99, 0.01],  
    "1% heads": [0.01, 0.99]  
}
```

```
for name, p in coins.items():  
    print(name, "Entropy =", round(entropy(p), 3), "bits")
```
